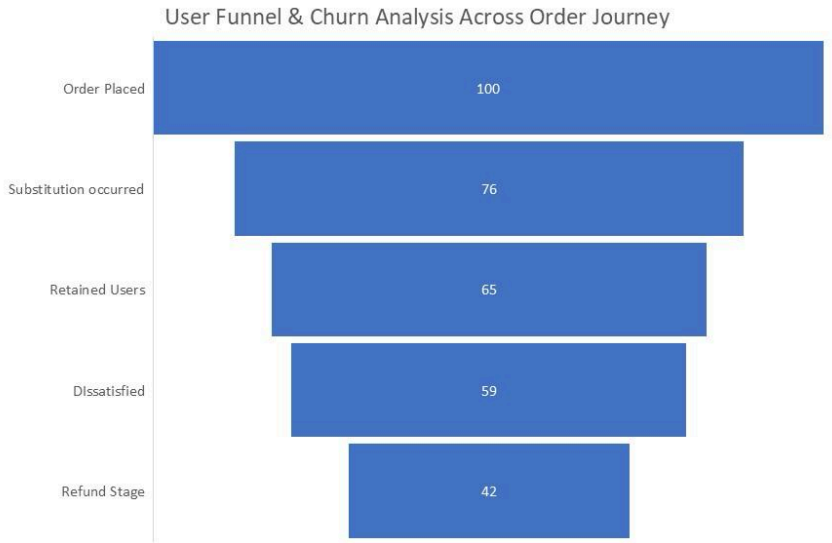
1. Funnel Analysis



Description:

This funnel illustrates user progression from order placement through substitution, dissatisfaction, complaint/refund stages, and eventual retention. It highlights where users experience friction and drop off during the post-order journey.

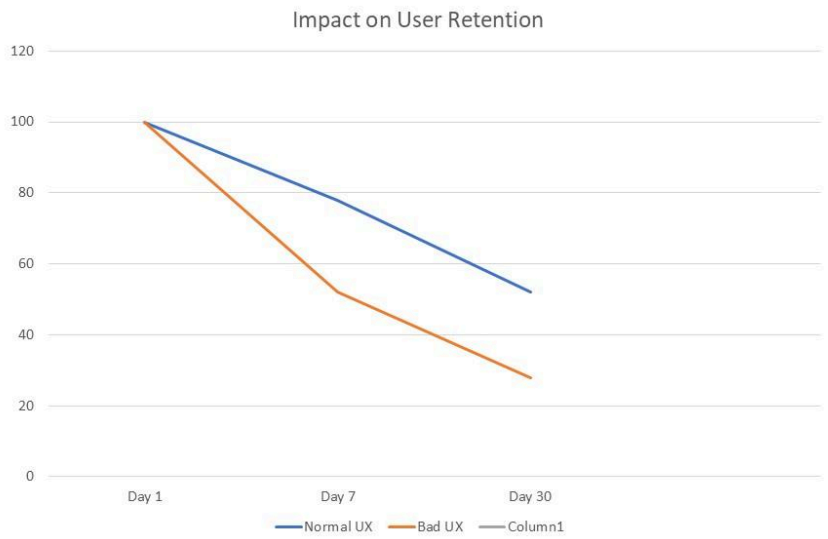
Analytical Interpretation:

A significant proportion of users encounter substitutions (76%), of which a large subset becomes dissatisfied (59%). The transition from dissatisfaction to complaint/refund (42%) indicates escalation of negative experience.

Key Result:

> A 35% drop-off is observed before the retention stage, indicating that substitution and refund-related friction are primary drivers of user churn.

2. Retention Analysis



Description:

This chart compares retention rates over time between users with a normal experience and those exposed to substitution or refund-related issues.

Analytical Interpretation:

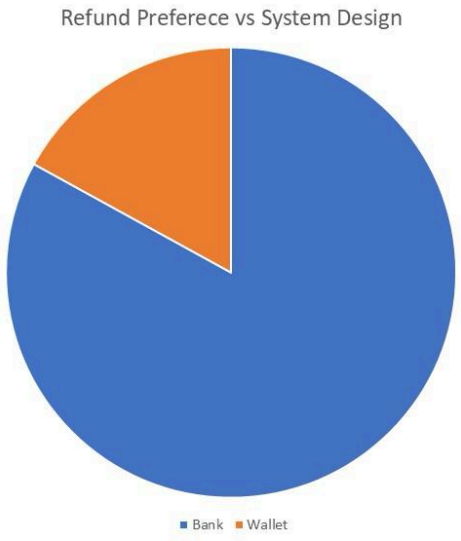
While both cohorts start at 100%, the retention curve for users with negative experiences declines at a significantly steeper rate, particularly within the first 7 days.

Key Result:

> Users exposed to poor experience exhibit approximately 46% lower retention by Day 30, demonstrating a strong negative impact on long-term engagement.

Cohort analysis tracks user behavior over time to evaluate product stickiness.

3. Refund System Misalignment



Description:

This chart presents the distribution of user preference between direct bank refunds and wallet-based refunds.

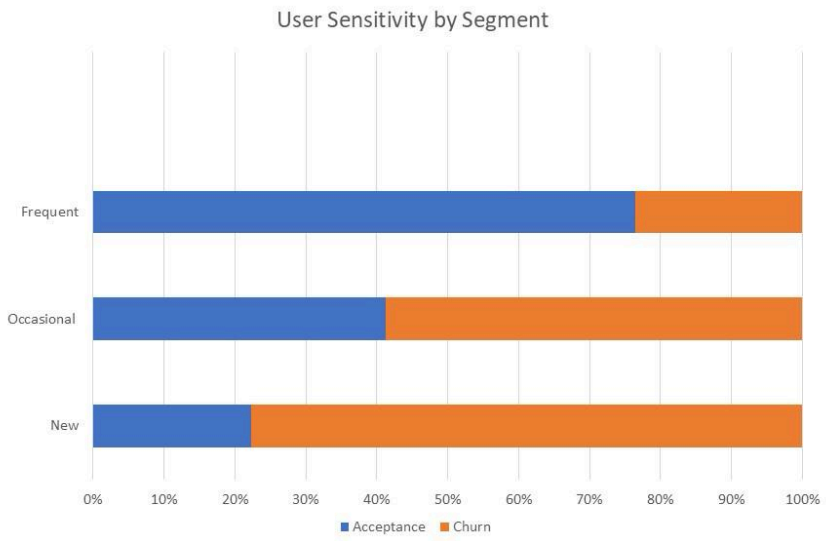
Analytical Interpretation:

A clear majority of users (83%) prefer refunds to their original payment method, while only a small fraction are comfortable with wallet credits.

Key Result:

> The current wallet-based refund system is misaligned with user expectations, creating a structural source of dissatisfaction.

4. User Segmentation



Description:

This chart segments users based on usage frequency and shows their respective tolerance to substitution and refund-related friction.

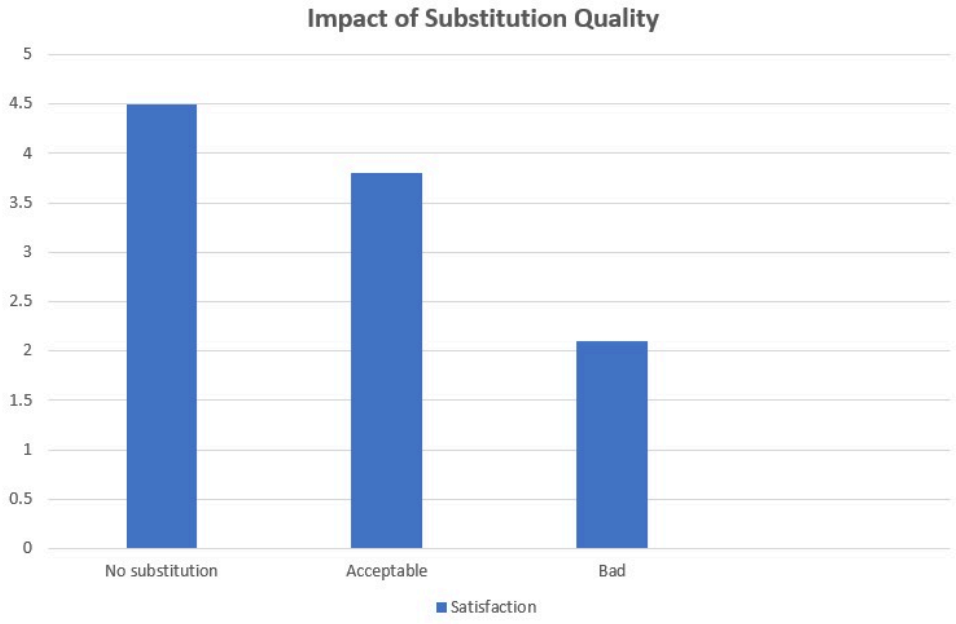
Analytical Interpretation:

New users exhibit the highest churn risk (70%) and lowest acceptance of wallet refunds, while frequent users demonstrate higher tolerance due to established platform familiarity.

Key Result:

> New users are approximately 3.5 times more likely to churn, indicating that current product design disproportionately impacts early-stage user retention.

5. Satisfaction Analysis



Description:

This chart compares user satisfaction scores across different substitution scenarios: no substitution, acceptable substitution, and poor substitution.

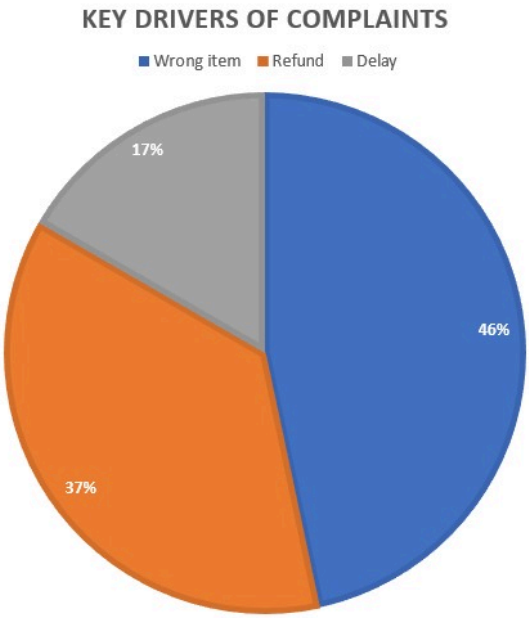
Analytical Interpretation:

Satisfaction decreases progressively as substitution quality deteriorates, with a sharp decline in the case of poor substitutions.

Key Result:

> Poor substitutions reduce satisfaction by more than 50%, highlighting the importance of maintaining product reliability.

6. Complaint Analysis



Description:

This chart categorizes user complaints into primary issue types, including incorrect items, refund dissatisfaction, and delivery delays.

Analytical Interpretation:

A majority of complaints are concentrated around substitution (wrong item) and refund-related issues, while other factors contribute significantly less.

Key Result:

> Approximately 75% of complaints originate from substitution and refund issues, indicating high problem concentration in these areas.

7. Business Impact

Unit Economics Framework:

> Revenue = Users × Average Order Value × Retention

Description:

This metric quantifies the daily revenue exposure resulting from churn caused by substitution and refund dissatisfaction.

Analytical Interpretation:

Given user base, average order value, and observed churn rates, a substantial portion of potential revenue is lost due to retention failure.

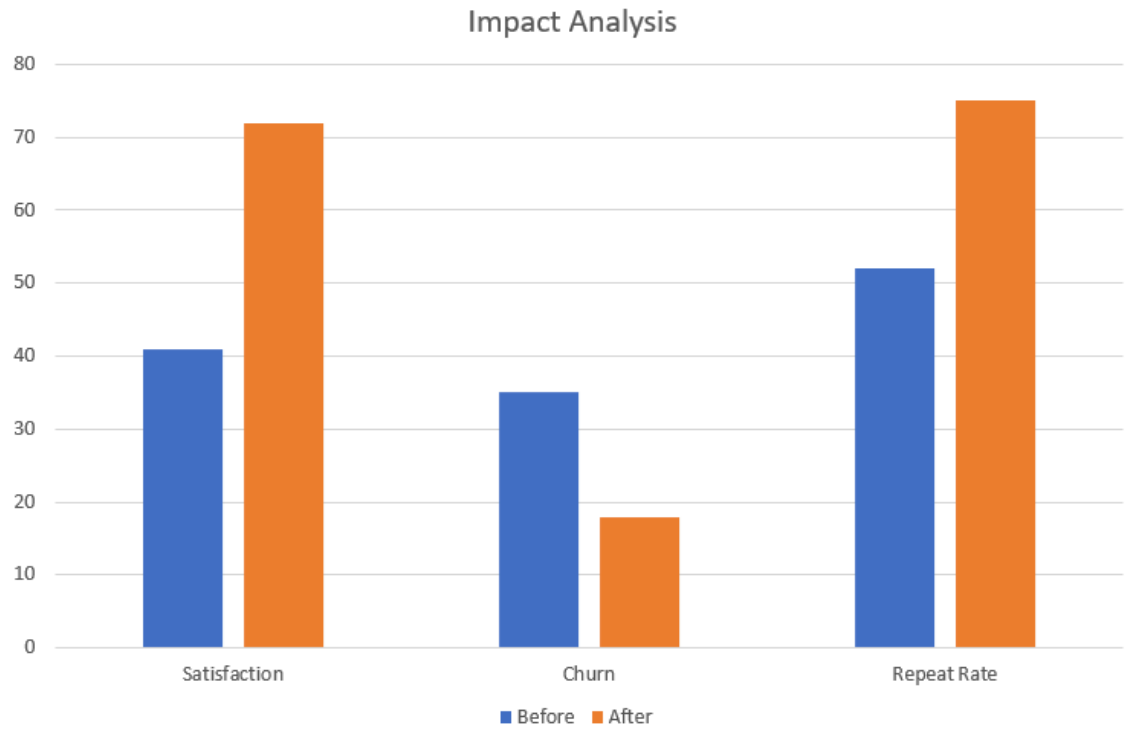
Key Result:

> Approximately ₹14M per day is at risk, demonstrating that user experience issues have direct and significant business implications.

Display: KPI Highlight

₹14M/day revenue at risk

8. Projected Impact



Description:

This chart compares key performance metrics before and after the implementation of proposed product solutions.

Analytical Interpretation:

Improvements in substitution control and refund flexibility lead to measurable gains in satisfaction and repeat usage, while significantly reducing churn.

Key Result:

> Churn is reduced by approximately 50%, while satisfaction and repeat purchase rates increase substantially, indicating strong potential ROI from proposed changes.
